

# Unit 08

## Files, Streams and Object Serialization

CMPS 251, Fall 2020, Dr. Abdulaziz Al-Ali

# Check point (for previous unit)

---

- ▶ What are layout managers? What do they do?
- ▶ Describe these:
  - ▶ GridPane
  - ▶ FlowPane
  - ▶ BorderPane

# Objectives

---

- ▶ Reading and writing text files
- ▶ Reading and writing objects in binary files

# Overview

---

- ▶ Data stored in your program is temporary
  - ▶ Arrays, variables, etc
- ▶ When the program ends, all the data is lost
- ▶ To store data between program runs, we use files
- ▶ Java has MANY ways to read and write files
  - ▶ In these slides we'll only use a few of them

# Files and Streams

---

- ▶ Java programs perform file processing by using classes from package **java.io**.
- ▶ Includes definitions for stream classes
  - ▶ **FileInputStream** (for byte-based input from a file)
  - ▶ **FileOutputStream** (for byte-based output to a file)
  - ▶ **FileReader** (for character-based input from a file)
  - ▶ **FileWriter** (for character-based output to a file)
- ▶ You open a file by creating an object of one of these stream classes. The object's constructor opens the file.

# Writing to a **Text** File:

## **Formatter** Class

---

- ▶ **Formatter** outputs formatted Strings to the specified stream
- ▶ **Constructors:**
  - ▶ One argument of type **File**
  - ▶ ...

# Writing to a Text File: Example

```
import java.util.Formatter;
import java.io.File;
import java.io.IOException;

public class SimpleFormatter {
    Formatter out;

    public SimpleFormatter() {
        try {
            out = new Formatter(new File("MyOutFile.txt"));
        } catch (IOException ioe) {
            System.out.println("File is not opened. Exception occurred..\n"
                               + ioe);

            return;
        }

        out.format("Hi there, this is being written to a file.\n");

        for(int i=0; i < 10; i++) {
            out.format("%d\n", i);
        }

        out.close();
    }
}
```

We give it a File object

*format()* method writes the content into the file.

## Writing to a Text File: Exceptions

---

- ▶ A **SecurityException** occurs if the user does not have permission to write data to the file.
- ▶ A **FileNotFoundException** occurs if the file does not exist and a new file cannot be created.

# Reading From a **Text** File: Scanner Class

---

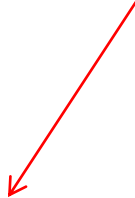

- ▶ Class **Scanner** can be used to retrieve data sequentially from a file
- ▶ Constructors:
  - ▶ One argument **System.in** which we have been using to read from the standard input device of your system, the keyboard by default.
  - ▶ One argument a **File** object resulting in the methods of scanner to be invoked on the file specified.
  - ▶ ...
- ▶ Browse the **API doc** files of the **Scanner** class for more explanations.

# Reading From a Text File: Example

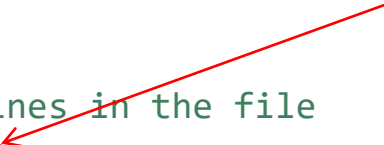

---

```
import java.io.File;
import java.io.FileNotFoundException;
import java.util.Scanner;
public class SimpleScanner {
    Scanner in1;
    public SimpleScanner() {
        try {
            in1 = new Scanner(new File("myData.txt"));
        } catch (FileNotFoundException fnfe) {
            System.out.println(fnfe);
            return;
        }
        // Read and print out all lines in the file
        while (in1.hasNextLine()) {
            System.out.println(in1.nextLine());
        }
        if (in1 != null) in1.close();
    }
}
```

We give it a File object instead of System.in

Checks whether we have more stuff to read from the file

# Reading From a Text File: Comments

---

- ▶ You can use any of the scanner methods you'd like
  - ▶ `nextInt()`, `nextFloat()`, etc.
- ▶ Frequently you just read in lines from the file and process them as strings

# Demo

---

- ▶ Formatter ([see JavaFormatter.java](#))
- ▶ Scanner ([see JavaScanner.java](#))

# Warm up

---

- ▶ Why do we need to output information to files?
- ▶ How many ways can we write to files?
- ▶ Which class do we use to write formatted text files?
- ▶ When does Java actually try to open a file?

# File Class: Constructors

---

- ▶ File has four constructors:

**File**(**File** parent, **String** child)

Creates a new **File** instance from a parent abstract pathname and a child pathname string.

**File**(**String** pathname)

Creates a new **File** instance by converting the given pathname string into an abstract pathname.

**File**(**String** parent, **String** child)

Creates a new **File** instance from a parent pathname string and a child pathname string.

**File**(**URI** uri)

Creates a new **File** instance by converting the given file: URI into an abstract pathname.

- ▶ **A Uniform Resource Identifier (URI)** is a more general form of the **Uniform Resource Locators (URLs)** that are used to locate websites.

Note: abstract pathname = File object

# File Class: Some Methods

---

boolean	<a href="#"><code>delete()</code></a> Deletes the file or directory denoted by this abstract pathname.
boolean	<a href="#"><code>exists()</code></a> Tests whether the file or directory denoted by this abstract pathname exists.
<a href="#"><code>String</code></a>	<a href="#"><code>getAbsolutePath()</code></a> Returns the absolute pathname string of this abstract pathname.
<a href="#"><code>String</code></a>	<a href="#"><code>getName()</code></a> Returns the name of the file or directory denoted by this abstract pathname.
<a href="#"><code>String</code></a>	<a href="#"><code>getParent()</code></a> Returns the pathname string of this abstract pathname's parent, or null if this pathname does not name a parent directory.
<a href="#"><code>File</code></a>	<a href="#"><code>getParentFile()</code></a> Returns the abstract pathname of this abstract pathname's parent, or null if this pathname does not name a parent directory.
<a href="#"><code>String</code></a>	<a href="#"><code>getPath()</code></a> Converts this abstract pathname into a pathname string.
boolean	<a href="#"><code>isDirectory()</code></a> Tests whether the file denoted by this abstract pathname is a directory.
boolean	<a href="#"><code>isFile()</code></a> Tests whether the file denoted by this abstract pathname is a normal file.
long	<a href="#"><code>lastModified()</code></a> Returns the time that the file denoted by this abstract pathname was last modified.
long	<a href="#"><code>length()</code></a> Returns the length (size in Bytes) of the file denoted by this abstract pathname.
<a href="#"><code>String[]</code></a>	<a href="#"><code>list()</code></a> Returns an array of strings naming the files and directories in the directory denoted by this abstract pathname.
<a href="#"><code>File[]</code></a>	<a href="#"><code>listFiles()</code></a> Returns an array of abstract pathnames denoting the files in the directory denoted by this abstract pathname.
<a href="#"><code>File[]</code></a>	<a href="#"><code>listFiles(<a href="#"><code>FilenameFilter</code></a> filter)</code></a> Returns an array of abstract pathnames denoting the files and directories in the directory denoted by this abstract pathname that satisfy the specified filter.
boolean	<a href="#"><code>mkdir()</code></a> Creates the directory named by this abstract pathname.

Note: “abstract pathname” = *File* object.

# Separator Characters

---

A separator character is used to separate directories and files in the path.

- ▶ On Windows, it is a backslash (\).
  - ▶ Example: `C:\Users\dana\MyDocuments\...`
- ▶ On Linux/UNIX, it is a forward slash (/).
  - ▶ Example: `/home/dana/MyDocuments/...`
- ▶ Java processes both characters identically
- ▶ When building Strings that represent path information, you can use `File.separator` to obtain the local computer's proper separator.
  - ▶ This constant returns a String consisting of one character—the proper separator for the system.

# New Line Character

---

Different platforms use different line-separator characters.

- ▶ On **UNIX/Linux/Mac OS X**, it is a newline (**\n**)
- ▶ On **Windows**, it is a combination of a carriage return and a line feed (**\r\n**)
- ▶ You can use the **%n** format specifier in a format control string to output a platform-specific line separator
- ▶ Method `System.out.println` outputs a platform-specific line separator after its argument.
- ▶ Java can read either one transparently

# Check point

---

- ▶ When is a file opened by a Java program?
- ▶ Which of the following is used in Windows and which is used in Linux?
  - ▶ /
  - ▶ \
  - ▶ \n
  - ▶ \r\n
- ▶ Which method inside the File class checks if it is a directory?

# Demo

---

- ▶ File class usage ([see FileTester.java](#))
- ▶ FileReader/Writer ([see FileReaderWriter.java](#)) - optional

# Question!

---

- ▶ How would you store information about a Person class?
- ▶ Suppose we only have two members:
  - ▶ String name
  - ▶ int age
- ▶ Suppose every Person has a Pet., then what else should we include in our file?
- ▶ What if every Pet has a favorite Meal?

# Object Serialization

---

- ▶ Java object serialization is the ability to read, or write, an entire object from or to a file.
- ▶ A serialized object is represented as a sequence of bytes that includes the object's data and its type information
- ▶ After a serialized object has been written into a file, it can be read from the file and deserialized to recreate the object in memory
- ▶ Objects of classes that implement interface `Serializable` can be serialized and deserialized with `ObjectOutputStreams` and `ObjectInputStreams`

```
import java.io.Serializable;
class Person implements Serializable{
    //same body of the class Person as you used to code
    it
}
```

# Writing Objects to Binary Files

---

```
public class BinaryObjectWriter {  
    public BinaryObjectWriter() {  
        ObjectOutputStream out;  
        FileOutputStream fos;  
        Person p1, p2;  
  
        try {  
            fos = new FileOutputStream("myfile.obj");  
            out = new ObjectOutputStream(fos);  
  
            p1 = new Person("Ahmed");  
            p2 = new Person("Hind");  
  
            out.writeObject(p1);  
            out.writeObject(p2);  
            out.writeObject(null);  
            out.close();  
        } catch (IOException ioe) {  
            System.out.println(ioe);  
        }  
    }  
}
```

← Writing Person objects directly!

# Reading Objects from Binary Files

---

```
public class BinaryObjectReader {
    public BinaryObjectReader() {
        ObjectInputStream in;
        FileInputStream fis;
        try {
            Object obj;
            Person p;

            fis = new FileInputStream("myfile.obj");
            in = new ObjectInputStream(fis);

            while ((obj = in.readObject()) != null) {
                p = (Person) obj;
                System.out.println(p.getInfoLong());
            }

            in.close();
        } catch (IOException ioe) {
            System.out.println(ioe);
        } catch (ClassNotFoundException e) {
            System.out.println(e);
        }
    }
}
```

Reading Person objects directly! 

# For Fun: JFileChooser

- ▶ Class JFileChooser displays a dialog that enables the user to easily select files or directories.

- ▶ See sample code for an example

# For Fun: JFileChooser

---

- ▶ Two methods to keep in mind:
- ▶ `showOpenDialog(..)`
  - ▶ This method displays the chooser to the user
  - ▶ returns `JFileChooser.APPROVE_OPTION`
  - ▶ Or `JFileChooser.CANCEL_OPTION`
- ▶ `getSelectedFile()`
  - ▶ Returns the selected File abstract pathname.

What type  
are these  
returned  
values?!

# Demo

---

- ▶ See [SerializedObjects.java](#)

# Wisdom check

---

- ▶ What are the good and bad things about writing files as text?
- ▶ And as binary?

# Summary

---

- ▶ Files
- ▶ Reading and writing text files
- ▶ Reading and writing objects from binary files
